Biological Reference Interval

SEROLOGY

QuantiFERON- TB Gold

Method : Elisa

Specimen : Serum

0.001 IU/ml

<0.35 : Negative

>=0.35 : Positive

Note:

1. Magnitude of measured Gamma Interferon cannot be correlated with stage or degree of infection, level of immune responsiveness or likelihood of progression to active disease.

2. False negative results may be obtained if sample is taken prior to development of immune response. CDC recommends repeat test after 8-10 weeks in case of high suspicion of tuberculosis.

3. Immunocompromised patients can also show false negativity.

Comments:

This test is used as an aid in the diagnosis of latent & active tuberculosis but does not distinguish between the two forms of the disease. A positive result supports the diagnosis of tuberculosis; however infection by other mycobacteria like M. kansasii, M. szulgai, M. marinum can also show positivity. A complete medical & diagnostic evaluation is necessary to confirm/exclude tubercular infection.
